

Build a small backend system that shows clean structure, event-driven basics, and deployment understanding.

Tech Stack

Node.js + Express, MongoDB, Apache Kafka, Docker, REST APIs, DDD, and deploy on Amazon Web Services or Google Cloud Platform (free tier is fine).

What to Build

1. Structure (DDD) ✓

Organize the project in a simple DDD style:

- Domain ✓
- Application ✓
- Infrastructure ✓
- API layer ✓

2. REST API ✓

Build a simple system (Posts):

- Create item ✓
- Get item ✓
- List items ✓

3. MongoDB ✓

- Store data in MongoDB ✓
- Use clean repository pattern ✓

4. Kafka

Add simple event flow:

- When creating an item → send event to Kafka
- Consumer receives event and processes it (log or simple action)

5. Docker

- Dockerize the project
- Use docker-compose for:

- API
- MongoDB
- Kafka

6. Deployment

- Deploy the system on AWS or GCP
- Make it publicly accessible

What to Submit

1. GitHub repo (code + Docker + structure) ✓
2. README (how to run + short explanation) ✓
3. Postman collection ✓
4. Video (clear voice):
 - Explain project structure
 - Show API working
 - Show Kafka flow
 - Show deployed system

2.
